ABSTRACT

An opening and closing device includes a slide member in substantially ring shape placed in a contact area between a stator and a case, wherein a stator cam of the stator is elastically pushed by a rotor cam of a rotor
10 elastically urged by a spring, wherein the case in substantially tubular shape accommodates the constituent members inside thereof, wherein the slide member serves as a lubricant element and reduces friction between the stator and the case, hence the opening and closing device is provided with a light
operational feeling.
